Exceptions and Interrupts

- **“Unexpected” events requiring change in flow of control**
 - Different ISAs use the terms differently
 - Dealing with them without sacrificing performance is hard
- **Exception**
 - Arises within the CPU
 - E.g., undefined opcode, overflow, syscall, ...
- **Interrupts**
 - From an external I/O controller

Handling Exceptions (1)

▪ Handling exceptions in MIPS

- Exceptions managed by a System Control Coprocessor (CPO)
- Save PC of offending (or interrupted) instruction
 - In MIPS: Exception Program Counter (EPC)
- Save indication of the problem
 - In MIPS: Cause register
 - We'll assume 1-bit:
 - 0 for undefined opcode, 1 for overflow
- Jump to handler at `0x8000 0180`

Handling Exceptions (2)

■ An alternate mechanism

- Vectored interrupts
 - Handler address determined by the cause
- Example:
 - Undefined opcode: 0xC000 0000
 - Overflow: 0xC000 0020
 - ...: 0xC000 0040
- Instructions either
 - Deal with the interrupt, or
 - Jump to real handler

Handling Exceptions (3)

▪ Handler actions

- Read cause, and transfer to relevant handler
- Determine action required
- If restartable
 - Take corrective action
 - Use EPC to return to program
- Otherwise
 - Terminate program
 - Report error using EPC, cause, ...

Exceptions in a Pipeline

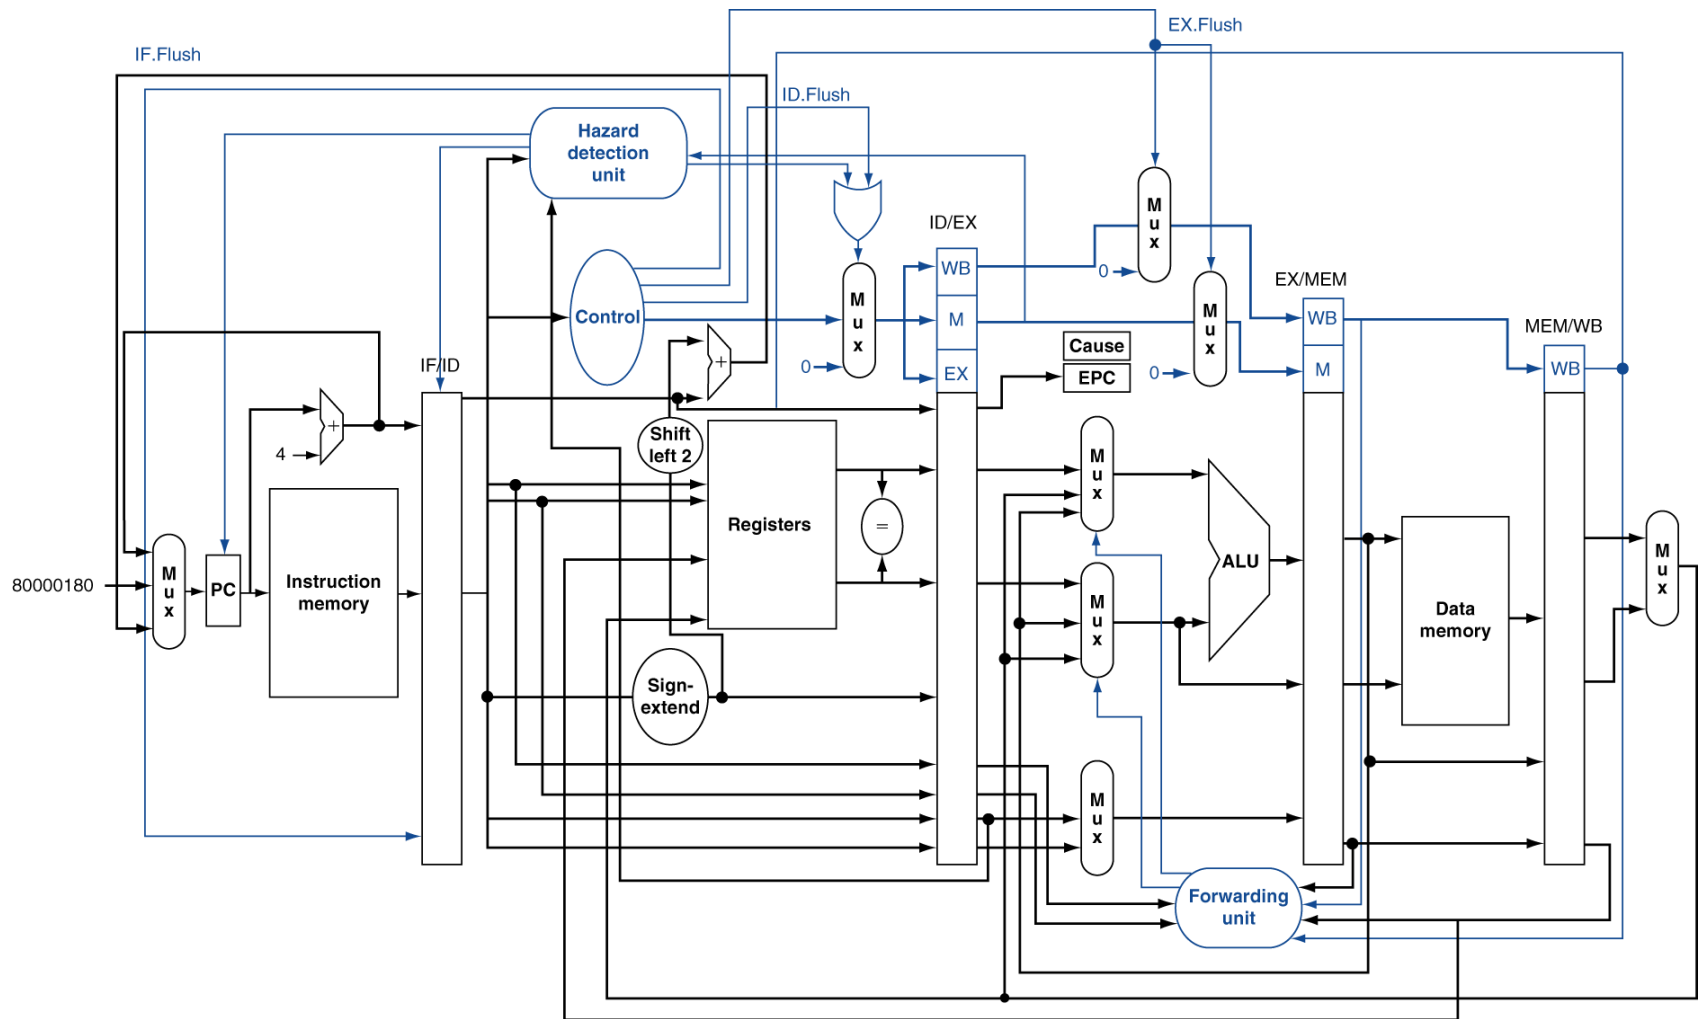

▪ Another form of control hazard

- Consider overflow on add in EX stage

```
add    $1, $2, $1
```

- Prevent \$1 from being clobbered
 - Complete previous instructions
 - Flush add and subsequent instructions
 - Set Cause and EPC register values
 - Transfer control to handler
- Similar to mispredicted branch
 - Use much of the same hardware

Pipeline with Exceptions

Exception Properties

▪ Restartable exceptions

- Pipeline can flush the instruction
- Handler executes, then returns to the instruction
 - Refetched and executed from scratch

▪ PC saved in EPC register

- Identifies causing instruction
- Actually PC + 4 is saved
 - Handler must adjust

Exception Example (1)

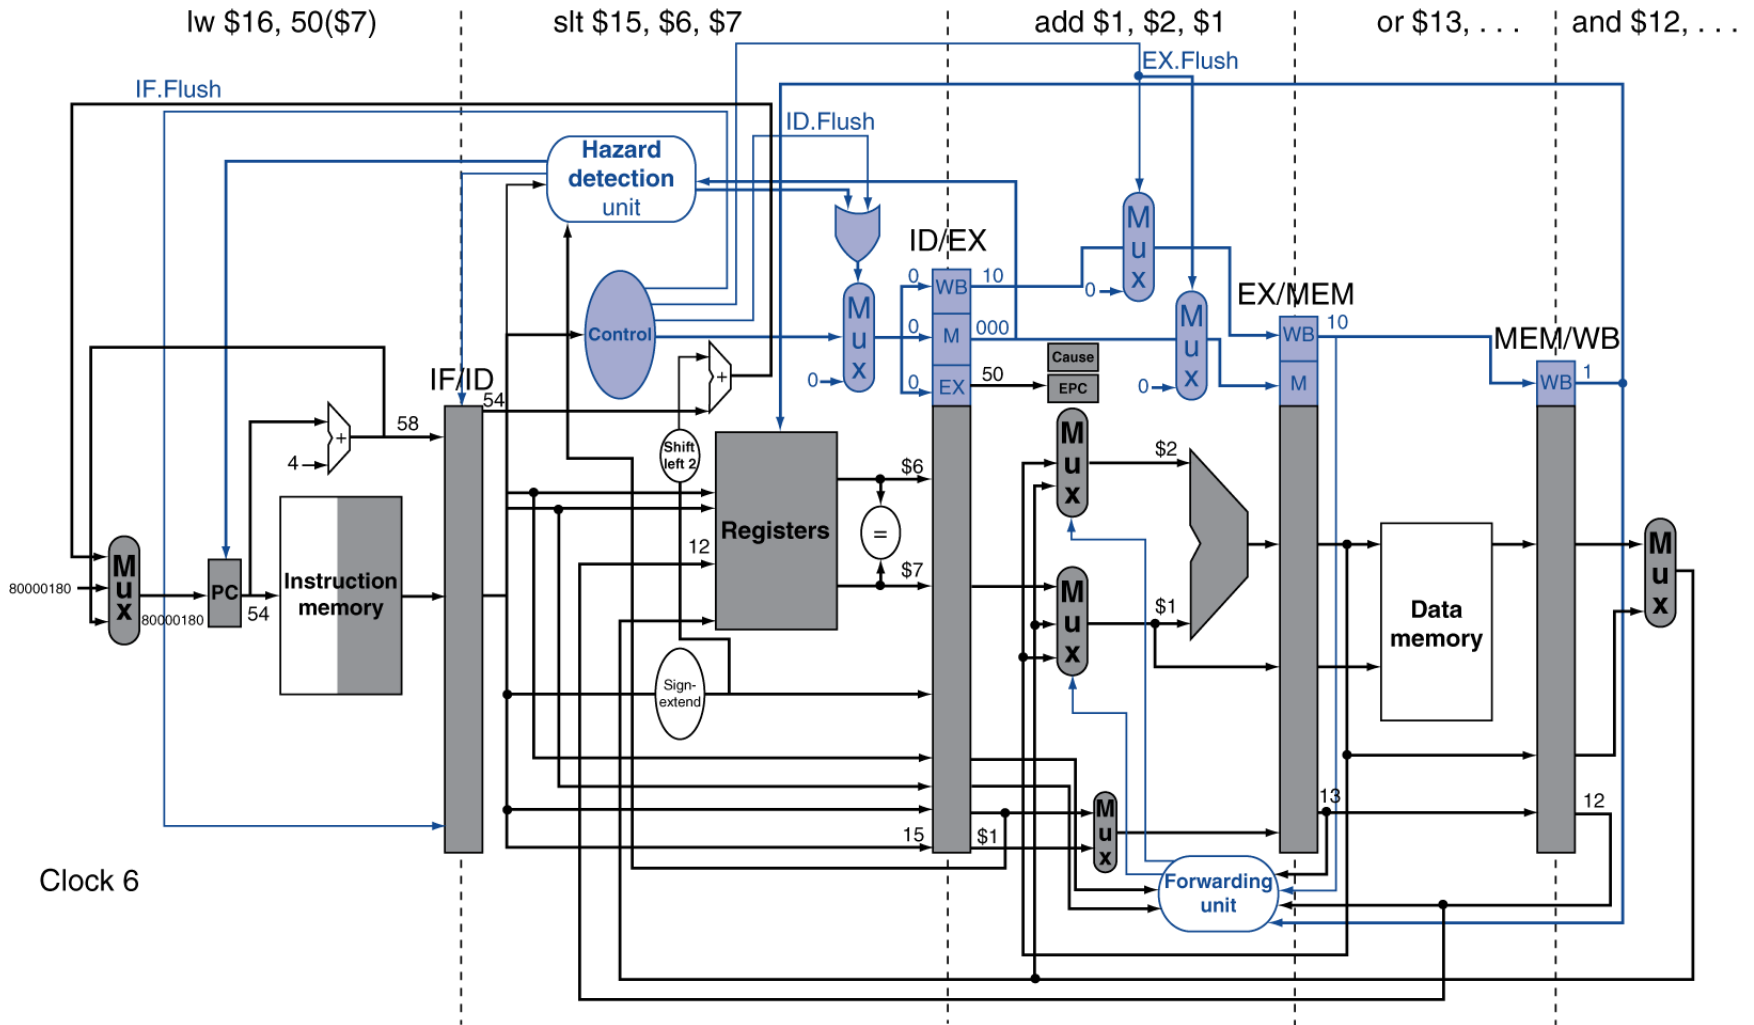

- Exception on add in

```
40:  sub  $11, $2, $4
44:  and  $12, $2, $5
48:  or   $13, $2, $6
4C:  add  $1,  $2, $1
50:  slt  $15, $6, $7
54:  lw   $16, 50($7)
... 
```

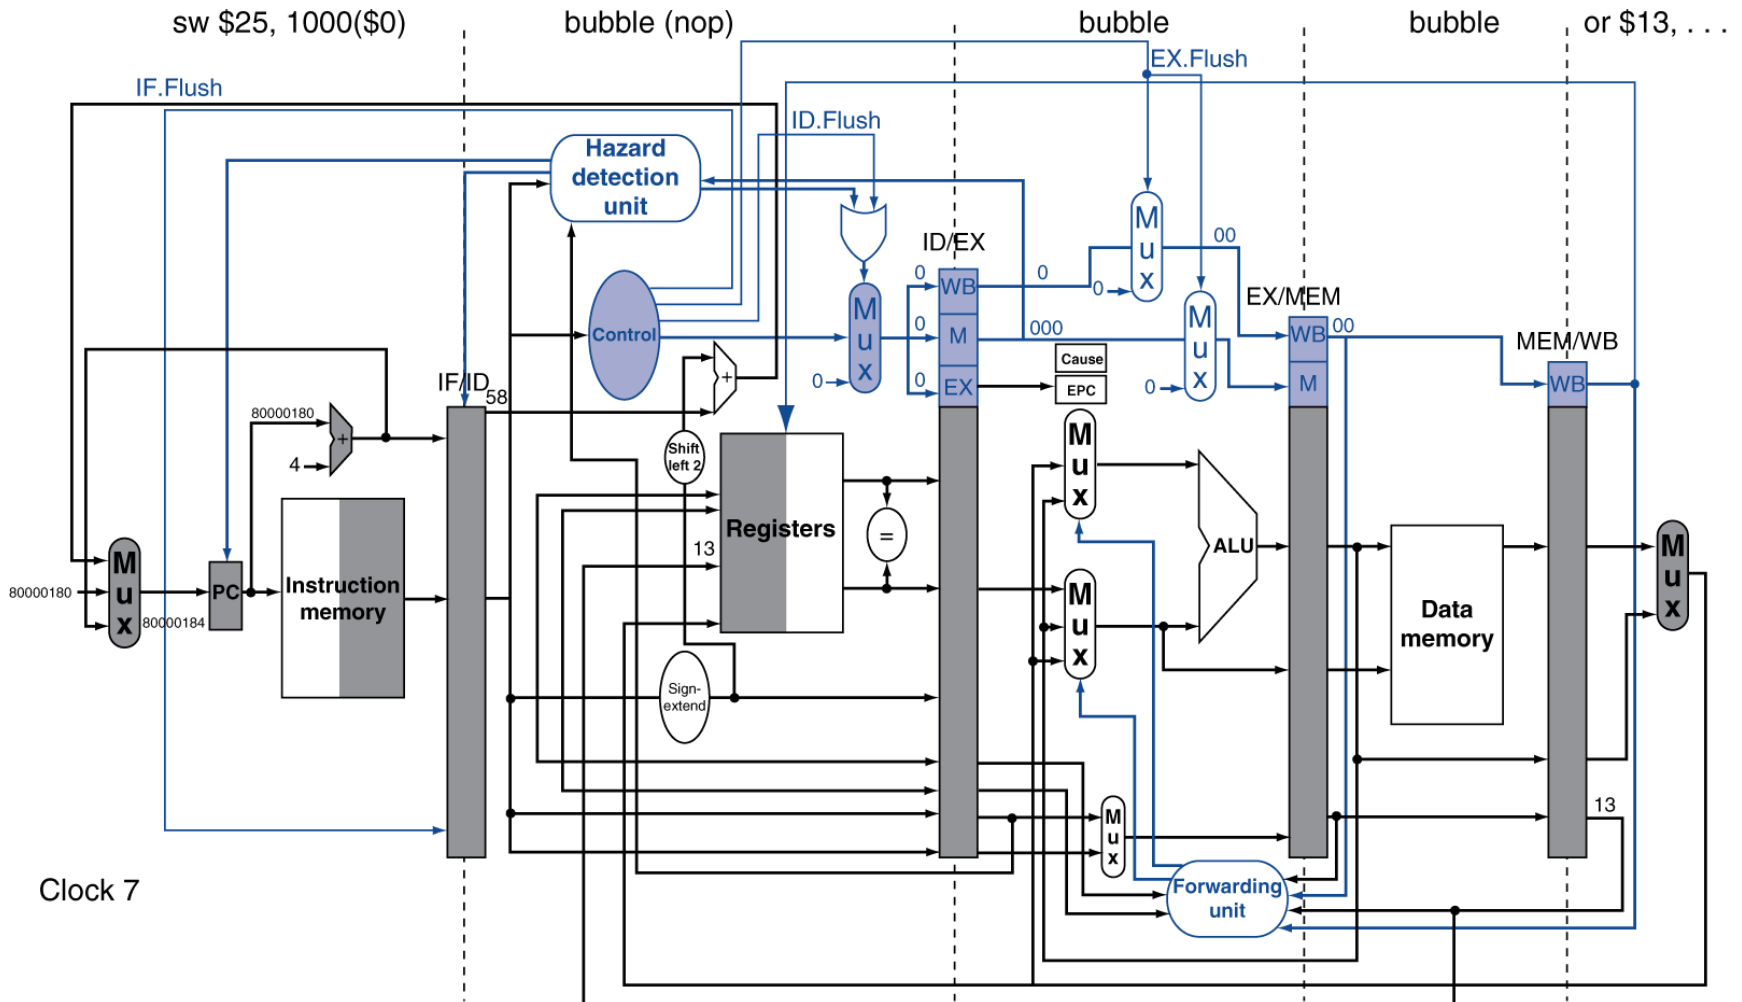

- Handler

```
80000180  SW  $25, 1000($0)
80000184  SW  $26, 1004($0)
... 
```

Exception Example (2)

Exception Example (3)

Multiple Exceptions

- **Pipelining overlaps multiple instructions**
 - Could have multiple exceptions at once
- **Simple approach: deal with exception from earliest instruction**
 - Flush subsequent instructions
 - "Precise" exceptions
- **In complex pipelines**
 - Multiple instructions issued per cycle
 - Out-of-order completion
 - Maintaining precise exceptions is difficult!

Imprecise Exceptions

■ Imprecise exceptions

- Just stop pipeline and save state
 - Including exception cause(s)
- Let the handler work out
 - Which instruction(s) had exceptions
 - Which to complete or flush
 - » May require “manual” completion
- Simplifies hardware, but more complex handler software
- Not feasible for complex multiple-issue out-of-order pipelines
