Computer Abstractions and Technology

Euiseong Seo (euiseong@skku.edu)
Computer Systems Laboratory
Sungkyunkwan University
http://csl.skku.edu
The Computer Revolution

- **Progress in computer technology**
  - Underpinned by Moore’s Law

- **Makes novel applications feasible**
  - Computers in automobiles
  - Cell phones
  - Human genome project
  - World Wide Web
  - Search Engines

- **Computers are pervasive**
Classes of Computers

- Desktop computers
  - General purpose, variety of software
  - Subject to cost/performance tradeoff

- Server computers
  - Network based
  - High capacity, performance, reliability
  - Range from small servers to building sized

- Embedded computers
  - Hidden as components of systems
  - Stringent power/performance/cost constraints
The Processor Market

[Bar chart showing the market share of cell phones, PCs, and TVs from 1997 to 2007. The y-axis represents the market share, ranging from 0 to 1200, and the x-axis represents the years from 1997 to 2007.]
What You Will Learn

- How programs are translated into the machine language
  - And how the hardware executes them
- The hardware/software interface
- What determines program performance
  - And how it can be improved
- How hardware designers improve performance
- What is parallel processing
Understanding Performance

- **Algorithm**
  - Determines number of operations executed

- **Programming language, compiler, architecture**
  - Determine number of machine instructions executed per operation

- **Processor and memory system**
  - Determine how fast instructions are executed

- **I/O system (including OS)**
  - Determines how fast I/O operations are executed
Below Your Program

- **Application software**
  - Written in high-level language

- **System software**
  - Compiler: translates HLL code to machine code
  - Operating System: service code
    - Handling input/output
    - Managing memory and storage
    - Scheduling tasks & sharing resources

- **Hardware**
  - Processor, memory, I/O controllers
Levels of Program Code

- **High-level language**
  - Level of abstraction closer to problem domain
  - Provides for productivity and portability
- **Assembly language**
  - Textual representation of instructions
- **Hardware representation**
  - Binary digits (bits)
  - Encoded instructions and data
Components of a Computer

- **Same components for all kinds of computer**
  - Desktop, server, embedded

- **Input/output includes**
  - User-interface devices
    - Display, keyboard, mouse
  - Storage devices
    - Hard disk, CD/DVD, flash
  - Network adapters
    - For communicating with other computers
Anatomy of a Computer

- Output device
- Network cable
- Input device
- Input device
Anatomy of a Mouse

- **Optical mouse**
  - LED illuminates desktop
  - Small low-res camera
  - Basic image processor
    - Looks for x, y movement
  - Buttons & wheel
- **Supersedes roller-ball mechanical mouse**
Through the Looking Glass

- LCD screen: picture elements (pixels)
  - Mirrors content of frame buffer memory
Opening the Box
Inside the Processor (CPU)

- Datapath: performs operations on data
- Control: sequences datapath, memory, ...
- Cache memory
  - Small fast SRAM memory for immediate access to data
Inside the Processor

- AMD Barcelona: 4 processor cores
Abstractions

The BIG Picture

- Abstraction helps us deal with complexity
  - Hide lower-level detail
- Instruction set architecture (ISA)
  - The hardware/software interface
- Application binary interface
  - The ISA plus system software interface
- Implementation
  - The details underlying and interface
A Safe Place for Data

- **Volatile main memory**
  - Loses instructions and data when power off

- **Non-volatile secondary memory**
  - Magnetic disk
  - Flash memory
  - Optical disk (CDROM, DVD)
Networks

- Communication and resource sharing
- Local area network (LAN): Ethernet
  - Within a building
- Wide area network (WAN: the Internet)
- Wireless network: WiFi, Bluetooth
Technology Trends

- Electronics technology continues to evolve
  - Increased capacity and performance
  - Reduced cost

Defining Performance

- Which airplane has the best performance?

### Performance Graphs

#### Passenger Capacity
- Boeing 777
- Boeing 747
- BAC/Sud Concorde
- Douglas DC-8-50

#### Cruising Range (miles)
- Boeing 777
- Boeing 747
- BAC/Sud Concorde
- Douglas DC-8-50

#### Cruising Speed (mph)
- Boeing 777
- Boeing 747
- BAC/Sud Concorde
- Douglas DC-8-50

#### Passengers x mph
- Boeing 777
- Boeing 747
- BAC/Sud Concorde
- Douglas DC-8-50
Response Time and Throughput

- **Response time**
  - How long it takes to do a task

- **Throughput**
  - Total work done per unit time
    - e.g., tasks/transactions/… per hour

- **How are response time and throughput affected by**
  - Replacing the processor with a faster version?
  - Adding more processors?

- **We’ll focus on response time for now…**
Relative Performance

- Define Performance = 1/Execution Time
- “X is \( n \) time faster than Y”

\[
\text{Performance}_X / \text{Performance}_Y = \frac{\text{Execution time}_Y}{\text{Execution time}_X} = n
\]

Example: time taken to run a program

- 10s on A, 15s on B
- Execution Time\(_B\) / Execution Time\(_A\) = 15s / 10s = 1.5
- So A is 1.5 times faster than B
Measuring Execution Time

- **Elapsed time**
  - Total response time, including all aspects
    - Processing, I/O, OS overhead, idle time
  - Determines system performance

- **CPU time**
  - Time spent processing a given job
    - Discounts I/O time, other jobs’ shares
  - Comprises user CPU time and system CPU time
  - Different programs are affected differently by CPU and system performance
CPU Clocking

- Operation of digital hardware governed by a constant-rate clock

Clock period: duration of a clock cycle
- e.g., 250ps = 0.25ns = 250×10^{-12}s

Clock frequency (rate): cycles per second
- e.g., 4.0GHz = 4000MHz = 4.0×10^9Hz
CPU Time

CPU Time = CPU Clock Cycles \times \text{Clock Cycle Time}

\begin{align*}
\text{CPU Clock Cycles} &= \frac{\text{CPU Clock Cycles}}{\text{Clock Rate}}
\end{align*}

- **Performance improved by**
  - Reducing number of clock cycles
  - Increasing clock rate
  - Hardware designer must often trade off clock rate against cycle count
CPU Time Example

- Computer A: 2GHz clock, 10s CPU time
- Designing Computer B
  - Aim for 6s CPU time
  - Can do faster clock, but causes $1.2 \times$ clock cycles
- How fast must Computer B clock be?

$$
\text{Clock Rate}_B = \frac{\text{Clock Cycles}_B}{\text{CPU Time}_B} = \frac{1.2 \times \text{Clock Cycles}_A}{6s}
$$

$$
\text{Clock Cycles}_A = \text{CPU Time}_A \times \text{Clock Rate}_A
= 10s \times 2GHz = 20 \times 10^9
$$

$$
\text{Clock Rate}_B = \frac{1.2 \times 20 \times 10^9}{6s} = \frac{24 \times 10^9}{6s} = 4GHz
$$
Instruction Count and CPI

Clock Cycles = Instruction Count × Cycles per Instruction

CPU Time = Instruction Count × CPI × Clock Cycle Time

\[
\text{CPU Time} = \frac{\text{Instruction Count} \times \text{CPI}}{\text{Clock Rate}}
\]

- **Instruction Count for a program**
  - Determined by program, ISA and compiler

- **Average cycles per instruction**
  - Determined by CPU hardware
  - If different instructions have different CPI
    - Average CPI affected by instruction mix
CPI Example

- Computer A: Cycle Time = 250ps, CPI = 2.0
- Computer B: Cycle Time = 500ps, CPI = 1.2
- Same ISA
- Which is faster, and by how much?

\[
\text{CPU Time}_A = \text{Instruction Count} \times \text{CPI}_A \times \text{Cycle Time}_A = l \times 2.0 \times 250\text{ps} = l \times 500\text{ps} \\
\text{CPU Time}_B = \text{Instruction Count} \times \text{CPI}_B \times \text{Cycle Time}_B = l \times 1.2 \times 500\text{ps} = l \times 600\text{ps}
\]

\[
\frac{\text{CPU Time}_B}{\text{CPU Time}_A} = \frac{l \times 600\text{ps}}{l \times 500\text{ps}} = 1.2
\]

A is faster… …by this much
CPI in More Detail

- If different instruction classes take different numbers of cycles

\[
\text{Clock Cycles} = \sum_{i=1}^{n} (\text{CPI}_i \times \text{Instruction Count}_i)
\]

- Weighted average CPI

\[
\text{CPI} = \frac{\text{Clock Cycles}}{\text{Instruction Count}} = \sum_{i=1}^{n} \left( \text{CPI}_i \times \frac{\text{Instruction Count}_i}{\text{Instruction Count}} \right)
\]

Relative frequency
CPI Example

- Alternative compiled code sequences using instructions in classes A, B, C

<table>
<thead>
<tr>
<th>Class</th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPI for class</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>IC in sequence 1</td>
<td>2</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>IC in sequence 2</td>
<td>4</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

- Sequence 1: IC = 5
  - Clock Cycles
    \[= 2 \times 1 + 1 \times 2 + 2 \times 3\]
    \[= 10\]
  - Avg. CPI = \(\frac{10}{5} = 2.0\)

- Sequence 2: IC = 6
  - Clock Cycles
    \[= 4 \times 1 + 1 \times 2 + 1 \times 3\]
    \[= 9\]
  - Avg. CPI = \(\frac{9}{6} = 1.5\)
Performance Summary

The BIG Picture

\[
\text{CPU Time} = \frac{\text{Instructions}}{\text{Program}} \times \frac{\text{Clock cycles}}{\text{Instruction}} \times \frac{\text{Seconds}}{\text{Clock cycle}}
\]

- Performance depends on
  - Algorithm: affects IC, possibly CPI
  - Programming language: affects IC, CPI
  - Compiler: affects IC, CPI
  - Instruction set architecture: affects IC, CPI, \( T_c \)
In CMOS IC technology

$$\text{Power} = \text{Capacitive load} \times \text{Voltage}^2 \times \text{Frequency}$$

- $\times 30$
- $5V \rightarrow 1V$
- $\times 1000$
Reducing Power

- Suppose a new CPU has
  - 85% of capacitive load of old CPU
  - 15% voltage and 15% frequency reduction

\[
\frac{P_{\text{new}}}{P_{\text{old}}} = \frac{C_{\text{old}} \times 0.85 \times (V_{\text{old}} \times 0.85)^2 \times F_{\text{old}} \times 0.85}{C_{\text{old}} \times V_{\text{old}}^2 \times F_{\text{old}}} = 0.85^4 = 0.52
\]

- The power wall
  - We can’t reduce voltage further
  - We can’t remove more heat

- How else can we improve performance?
Uniprocessor Performance

§1.6 The Sea Change: The Switch to Multiprocessors

Constrained by power, instruction-level parallelism, memory latency
Multiprocessors

- Multicore microprocessors
  - More than one processor per chip
- Requires explicitly parallel programming
  - Compare with instruction level parallelism
    - Hardware executes multiple instructions at once
    - Hidden from the programmer
  - Hard to do
    - Programming for performance
    - Load balancing
    - Optimizing communication and synchronization
Yield: proportion of working dies per wafer
AMD Opteron X2 Wafer

- X2: 300mm wafer, 117 chips, 90nm technology
- X4: 45nm technology
Integrated Circuit Cost

Cost per die = \frac{\text{Cost per wafer}}{\text{Dies per wafer} \times \text{Yield}}

Dies per wafer \approx \frac{\text{Wafer area}}{\text{Die area}}

Yield = \frac{1}{(1 + (\text{Defects per area} \times \text{Die area}/2))^2}

- Nonlinear relation to area and defect rate
  - Wafer cost and area are fixed
  - Defect rate determined by manufacturing process
  - Die area determined by architecture and circuit design
SPEC CPU Benchmark

- Programs used to measure performance
  - Supposedly typical of actual workload
- Standard Performance Evaluation Corp (SPEC)
  - Develops benchmarks for CPU, I/O, Web, ...

- SPEC CPU2006
  - Elapsed time to execute a selection of programs
    - Negligible I/O, so focuses on CPU performance
  - Normalize relative to reference machine
  - Summarize as geometric mean of performance ratios
    - CINT2006 (integer) and CFP2006 (floating-point)
## CINT2006 for Opteron X4 2356

</tbody>
</table>
Pitfall: Amdahl’s Law

- Improving an aspect of a computer and expecting a proportional improvement in overall performance

\[ T_{\text{improved}} = \frac{T_{\text{affected}}}{\text{improvement factor}} + T_{\text{unaffected}} \]

- Example: multiply accounts for 80s/100s
  - How much improvement in multiply performance to get 5× overall?

\[ 20 = \frac{80}{n} + 20 \]

- Can’t be done!

- Corollary: make the common case fast
Fallacy: Low Power at Idle

- Look back at X4 power benchmark
  - At 100% load: 295W
  - At 50% load: 246W (83%)
  - At 10% load: 180W (61%)

- Google data center
  - Mostly operates at 10% – 50% load
  - At 100% load less than 1% of the time

- Consider designing processors to make power proportional to load
Pitfall: MIPS as a Performance Metric

- MIPS: Millions of Instructions Per Second
  - Doesn’t account for
    - Differences in ISAs between computers
    - Differences in complexity between instructions

\[
\text{MIPS} = \frac{\text{Instruction count}}{\text{Execution time} \times 10^6} = \frac{\text{Instruction count}}{\text{Instruction count} \times \text{CPI}} \times 10^6 = \frac{\text{Clock rate}}{\text{CPI} \times 10^6}
\]

- CPI varies between programs on a given CPU
Concluding Remarks

- Cost/performance is improving
  - Due to underlying technology development
- Hierarchical layers of abstraction
  - In both hardware and software
- Instruction set architecture
  - The hardware/software interface
- Execution time: the best performance measure
- Power is a limiting factor
  - Use parallelism to improve performance
