A Typical PC Bus Structure

- Monitor
- Processor
  - Cache
  - Memory
- Graphics controller
- Bridge/memory controller
- IDE disk controller
  - Disk
  - Disk
  - Disk
- SCSI controller
- SCSI bus
- Expansion bus interface
- Keyboard
- Parallel port
- Serial port
I/O Devices (1)

- **Block device**
  - Stores information in fixed-size blocks, each one with its own address.
  - 512B – 32KB per block
  - It is possible to read or write each block independently of all the other ones.
  - Disks, tapes, etc.

- **Character device**
  - Delivers or accepts a stream of characters.
  - Not addressable and no seek operation.
  - Printers, networks, mice, keyboards, etc.

I/O Devices (3)

- Device controller (or host adapter)
  - I/O devices have components:
    - Mechanical component
    - Electronic component
  - The electronic component is the device controller.
    - May be able to handle multiple devices.
  - Controller’s tasks
    - Convert serial bit stream to block of bytes.
    - Perform error correction as necessary.
    - Make available to main memory.
Accessing I/O Devices (1)

- **Direct I/O**
  - Use special I/O instructions to an I/O port address.

Accessing I/O Devices (2)

- Memory-mapped I/O
  - The device control registers are mapped into the address space of the processor.
    - The CPU executes I/O requests using the standard data transfer instructions.
  - I/O device drivers can be written entirely in C.
  - No special protection mechanism is needed to keep user processes from performing I/O
    - Can give a user control over specific devices but not others by simply including the desired pages in its page table.
  - Reading a device register and testing its value is done with a single instruction.
Polling vs. Interrupts (1)

- **Polled I/O**
  - CPU asks ("polls") devices if need attention.
    - ready to receive a command
    - command status, etc.
  - **Advantages**
    - Simple
    - Software is in control.
    - Efficient if CPU finds a device to be ready soon.
  - **Disadvantages**
    - Inefficient in non-trivial system (high CPU utilization).
    - Low priority devices may never be serviced.
Polling vs. Interrupts (2)

- **Interrupt-driven I/O**
  - I/O devices request interrupt when need attention.
  - Interrupt service routines specific to each device are invoked.
  - Interrupts can be shared between multiple devices.
  - **Advantages**
    - CPU only attends to device when necessary.
    - More efficient than polling in general.
  - **Disadvantages**
    - Excess interrupts slow (or prevent) program execution.
    - Overheads (may need 1 interrupt per byte transferred)
Polling vs. Interrupts (3)

1. CPU
   - device driver initiates I/O
   - CPU executing checks for interrupts between instructions
   - CPU receiving interrupt, transfers control to interrupt handler
   - interrupt handler processes data, returns from interrupt
   - CPU resumes processing of interrupted task

2. I/O controller
   - initiates I/O
   - input ready, output complete, or error generates interrupt signal

3. I/O controller

4. CPU

5. I/O controller

6. CPU

7. CPU
Polling vs. Interrupts (4)
Programmed I/O vs. DMA

- DMA (Direct Memory Access)
  - Bypasses CPU to transfer data directly between I/O device and memory.
  - Used to avoid programmed I/O for large data movement.
Blocking vs. Non-Blocking I/O

- **Blocking I/O**
  - Process is suspended until I/O completed.
  - Easy to use and understand.

- **Nonblocking I/O**
  - I/O call returns quickly, with a return value that indicates how many bytes were transferred.
  - A nonblocking read() returns immediately with whatever data available – the full number of bytes requested, fewer, or none at all.
Goals of I/O Software

- **Goals**
  - Device independence
  - Uniform naming
  - Error handling
  - Synchronous vs. asynchronous
  - Buffering
  - Sharable vs. dedicated devices

## Interrupt Handlers

### Handling interrupts

- **Critical actions**
  - Acknowledge an interrupt to the PIC.
  - Reprogram the PIC or the device controller.
  - Update data structures accessed by both the device and the processor.

- **Noncritical actions**
  - Update data structures that are accessed only by the processor.
    (e.g., reading the scan code from the keyboard)

- **Return from interrupts**
  - Actions may be delayed.
  - Copy buffer contents into the address space of some process (e.g., sending the keyboard line buffer to the terminal handler process).
  - **Bottom half (Linux)**
Device Drivers (1)

- Device drivers
  - Device-specific code to control each I/O device interacting with device-independent I/O software and interrupt handlers.
  - Requires to define a well-defined model and a standard interface of how they interact with the rest of the OS.
  - Implementing device drivers:
    - Statically linked with the kernel.
    - Selectively loaded into the system during boot time.
    - Dynamically loaded into the system during execution. (especially for hot pluggable devices).
Device Drivers (2)
The problem

- Reliability remains a crucial, but unresolved problem
  - 5% of Windows systems crash every day
  - Huge cost of failures: stock exchange, e-commerce, ...
  - Growing “unmanaged systems”: digital appliances, consumer electronics devices

- OS extensions are increasingly prevalent
  - 70% of Linux kernel code
  - Over 35,000 drivers with over 120,000 versions on Windows XP
  - Written by less experienced programmer

- Extensions are a leading cause of OS failure
  - Drivers cause 85% of Windows XP crashes
  - Drivers are 7 times buggier than the kernel in Linux
Device-Independent I/O SW (1)

- **Uniform interfacing for device drivers**
  - In Unix, devices are modeled as special files.
    - They are accessed through the use of system calls such as `open()`, `read()`, `write()`, `close()`, `ioctl()`, etc.
    - A file name is associated with each device.
  - Major device number locates the appropriate driver.
    - Minor device number (stored in i-node) is passed as a parameter to the driver in order to specify the unit to be read or written.
  - The usual protection rules for files also apply to I/O devices.
## Device-Independent I/O SW (2)

- **Buffering**
  - (a) Unbuffered
  - (b) Buffered in user space
  - (c) Buffered in the kernel space
  - (d) Double buffering in the kernel

![Diagram showing buffering methods](image)
Device-Independent I/O SW (3)

- **Error reporting**
  - Many errors are device-specific and must be handled by the appropriate driver, but the framework for error handling is device independent.
  - Programming errors vs. actual I/O errors
  - Handling errors
    - Returning the system call with an error code.
    - Retrying a certain number of times.
    - Ignoring the error.
    - Killing the calling process.
    - Terminating the system.
### Device-Independent I/O SW (4)

- **Allocating and releasing dedicated devices**
  - Some devices cannot be shared.
  1. Require processes to perform open()’s on the special files for devices directly.
     - The process retries if open() fails.
  2. Have special mechanisms for requesting and releasing dedicated devices.
     - An attempt to acquire a device that is not available blocks the caller.

- **Device-independent block size**
  - Treat several sectors as a single logical block.
  - The higher layers only deal with abstract devices that all use the same block size.
Provided as a library

- Standard I/O library in C
  - fopen() vs. open()?
  - Buffering for fgetc()?

Spooling

- A way of dealing with dedicated I/O devices in a multiprogramming system.
- Implemented by a daemon and a spooling directory.
- Printers, network file transfers, USENET news, mails, etc.
