QnA For PA #1
Multitasking

- Programmer’s model of multitasking

  - `fork()` spawns new process
    - Called once, returns twice

  - `exit()` terminates own process
    - Called once, never returns
      - Puts it into “zombie” status

  - `wait()` and `waitpid()` wait for and reap terminated children

  - `execve()` runs new program in existing process
    - Called once, (normally) never returns
Definition

- A signal is a small message that notifies a process that an event of some type has occurred in the system.
  - Kernel abstraction for exceptions and interrupts.
  - Sent from kernel (sometimes at the request of another process) to a process.
  - Different signals are identified by small integer ID’s.
  - The only information in a signal is its ID and the fact that it arrived.

</table>
Signal Concepts (1)

- **Sending a signal**
  - Kernel *sends* (delivers) a signal to a destination process by updating some state in the context of the destination process.
  - Kernel sends a signal for one of the following reasons:
    - Generated internally:
      » Divide-by-zero (*SIGFPE*)
      » Termination of a child process (*SIGCHLD*), ...
    - Generated externally:
      » *kill* system call by another process to request signal to the destination process.
Signal Concepts (2)

- Receiving a signal
  - A destination process receives a signal when it is forced by the kernel to react in some way to the delivery of the signal.
  - Three possible ways to react:
    - Explicitly ignore the signal
    - Execute the default action
    - Catch the signal by invoking signal-handler function
      » Akin to a hardware exception handler being called in response to an asynchronous interrupt.
Signal Concepts (3)

- **Default actions**
  - **Abort**
    - The process is destroyed
  - **Dump**
    - The process is destroyed & core dump
  - **Ignore**
    - The signal is ignored
  - **Stop**
    - The process is stopped
  - **Continue**
    - If the process is stopped, it is put into running state
Signal Concepts (4)

- **Signal semantics**
  - A signal is **pending** if it has been sent but not yet received.
    - There can be at most one pending signal of any particular type.
    - Signals are not queued!
  - A process can **block** the receipt of certain signals.
    - Blocked signals can be delivered, but will not be received until the signal is unblocked.
    - There is one signal that can not be blocked by the process. *(SIGKILL)* *(One more... SIGSTOP)*
  - A pending signal is received at most once.
    - Kernel uses a bit vector for indicating pending signals.
Signal Concepts (5)

- Implementation

  - Kernel maintains **pending** and **blocked** bit vectors in the context of each process.
    - **pending** – represents the set of pending signals
      » Kernel sets bit k in **pending** whenever a signal of type k is delivered.
      » Kernel clears bit k in **pending** whenever a signal of type k is received.
    - **blocked** – represents the set of blocked signals
      » Can be set and cleared by the application using the **sigprocmask** function.
Every process belongs to exactly one process group.

- **getpgrp()** – Return process group of current process
- **setpgid()** – Change process group of a process
Sending Signals (1)

- Sending signals from the keyboard
  - Typing `ctrl-c` (`ctrl-z`) sends a SIGINT (SIGTSTP) to every job in the foreground process group.
    - **SIGINT**: default action is to terminate each process.
    - **SIGTSTP**: default action is to stop (suspend) each process.
## Sending Signals (2)

- **int kill(pid_t pid, int sig)**
  - Can be used to send any signal to any process group or process.
    - `pid > 0`, signal `sig` is sent to `pid`.
    - `pid == 0`, `sig` is sent to every process in the process group of the current process.
    - `pid == -1`, `sig` is sent to every process except for process 1.
    - `pid < -1`, `sig` is sent to every process in the process group `-pid`
    - `sig == 0`, no signal is sent, but error checking is performed.

- **/bin/kill program sends arbitrary signal to a process or process group.**

  ```bash
  $ kill 10231 // SIGTERM : default signal
  $ kill -9 10231 // SIGKILL
  ```
Sending Signals (3)

```c
void fork12() {
    pid_t pid[N];
    int i, child_status;
    for (i = 0; i < N; i++)
        if ((pid[i] = fork()) == 0)
            while(1); /* Child infinite loop */

    /* Parent terminates the child processes */
    for (i = 0; i < N; i++) {
        printf("Killing process %d\n", pid[i]);
        kill(pid[i], SIGINT);
    }

    /* Parent reaps terminated children */
    for (i = 0; i < N; i++) {
        pid_t wpid = wait(&child_status);
        if (WIFEXITED(child_status))
            printf("Child %d terminated with exit status %d\n", wpid, WEXITSTATUS(child_status));
        else
            printf("Child %d terminated abnormally\n", wpid);
    }
}
```
Receiving Signals (1)

- Handling signals
  - Suppose kernel is returning from exception handler and is ready to pass control to process p.

  - Kernel computes $\text{pn} b = \text{pending} \& \sim \text{blocked}$
    - The set of pending non-blocked signals for process p
  - if ($\text{pn} b \neq 0$) {
    - Choose least nonzero bit k in $\text{pn} b$ and force process p to receive signal k.
    - The receipt of the signal triggers some action by p.
    - Repeat for all nonzero k in $\text{pn} b$.
  }

  - Pass control to next instruction in the logical flow for p.
Receiving Signals (2)

- Default actions
  - Each signal type has a predefined default action, which is one of:
    - The process terminates.
    - The process terminates and dumps core.
    - The process stops until restarted by a **SIGCONT** signal.
    - The process ignores the signal.
Installing Signal Handlers

- **sighandler_t signal (int sig, sighandler_t handler)**
  - typedef void (*sighandler_t)(int);
  - The signal function modifies the default action associated with the receipt of signal `sig`.

- **Different values for handler:**
  - SIG_IGN: ignore signals of type sig.
  - SIG_DFL: revert to the default action.
  - Otherwise, handler is the address of a signal handler.
    - Called when process receives signal of type `sig`.
    - Referred to as “installing” the signal handler.
    - Executing handler is called “catching” or “handling” the signal.
    - When the handler executes its return statement, control passes back to instruction in the control flow of the process that was interrupted by receipt of the signal.
Handling Signals (1)

- **Things to remember**
  - Pending signals are not queued.
    - For each signal type, just have single bit indicating whether or not signal is pending.
    - Even if multiple processes have sent this signal.
  - A newly arrived signal is blocked while the handler of the signal is running.
  - Sometimes system calls such as `read()` are not restarted automatically after they are interrupted by the delivery of a signal.
    - They return prematurely to the calling application with an error condition. `(errno == EINTR)`
Handling Signals (2)

- What is the problem of the following code?

```c
int ccount = 0;

void handler (int sig) {
    pid_t pid = wait(NULL);
    ccount--;
    printf ("Received signal %d from pid %d\n", sig, pid);
}

void fork14() {
    pid_t pid[N];
    int i;
    ccount = N;
    signal (SIGCHLD, handler);
    for (i = 0; i < N; i++)
        if ((pid[i] = fork()) == 0)
            /* child */
            exit(0);
    while (ccount > 0)
        sleep (5);
}
```
# Shell

## Definition

- An application program that runs programs on behalf of the user
  - sh: Original Unix Bourne Shell
  - csh: BSD Unix C Shell
  - tcsh: Enhanced C Shell
  - bash: Bourne-Again Shell

Execution is a sequence of read/evaluate steps

```c
int main()
{
    char cmdline[MAXLINE];

    while (1) {
        /* read */
        printf("> ");
        fgets(cmdline, MAXLINE, stdin);
        if (feof(stdin))
            exit(0);

        /* evaluate */
        eval(cmdline);
    }
}
```
void eval(char *cmdline) {
    char *argv[MAXARGS]; /* argv for execve() */
    int bg;              /* should the job run in bg or fg? */
    pid_t pid;           /* process id */

    bg = parseline(cmdline, argv);
    if (!builtin_command(argv)) {
        if ((pid = fork()) == 0) { /* child runs user job */
            if (execve(argv[0], argv, environ) < 0) {
                printf("%s: Command not found.\n", argv[0]);
                exit(0);
            }
        }
        if (!bg) { /* parent waits for fg job to terminate */
            int status;
            if (waitpid(pid, &status, 0) < 0)
                unix_error("waitfg: waitpid error");
        }
        else { /* otherwise, don’t wait for bg job */
            printf("%d %s", pid, cmdline);
        }
    }
}
**Simple Shell Example (2)**

- **Problem with Simple Shell example**
  - Shell correctly waits for and reaps foreground jobs.
  - But what about background jobs?
    - Will become zombies when they terminate.
    - Will never be reaped because shell (typically) will not terminate.
    - Creates a memory leak that will eventually crash the kernel when it runs out of memory.

- **Solution**
  - Reaping background jobs requires a mechanism called a *signal*. 
Exercise #1

- Deal with non-queueing signals

```c
int ccount = 0;

void handler (int sig) {
    pid_t pid = wait(NULL);
    ccount--;
    printf ("Received signal %d from pid %d\n", sig, pid);
}

void fork14() {
    pid_t pid[N];
    int i;
    ccount = N;
    signal (SIGCHLD, handler);
    for (i = 0; i < N; i++)
        if ((pid[i] = fork()) == 0)
            /* child */
            exit(0);
    while (ccount > 0)
        sleep (5);
}
```
Exercise #2

- React to externally generated events

- Make zombie process
  - When the process get ctrl+c signal from keyboard, it just prints “beep” to the monitor 5 times with 1-second interval
  - Print “I’m Alive!” to the monitor after 5-times beep
Exercise #3

- React to internally generated events

- Make alarm for every 1 second
  - Print “BEEP” for each second
  - Tip: alarm(int t) send SIGALRM after t seconds
